Lecture 7: Binary Search Tree (Cont.d), Midterm Review

Instructor: Pei Liu

# Some Notes

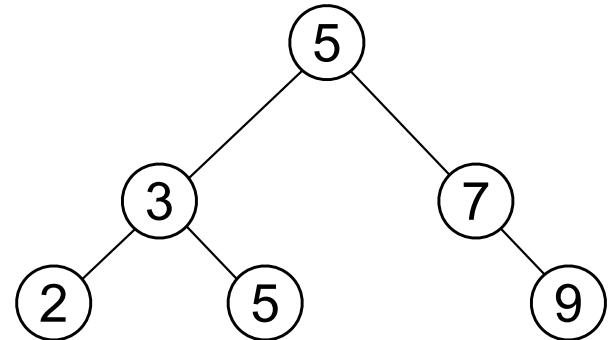

---

- ▶ Today's lecture will not be part of the midterm;
- ▶ Midterm this Sunday, between 9:30AM-12:00PM ET;
- ▶ If you are remote students, remember to connect before 9:15AM with camera turned on and your hands visible;
- ▶ Remote Students only: Questions will be distributed using Google form
  - ▶ You will get link to Google form on Friday
  - ▶ Don't fill the form before 9:30AM as the questions are not available
- ▶ Submit your answers via Gradescope section on course website

# Binary Search Tree Property

---

- ▶ Binary search tree property:
  - ▶ If  $y$  is in left subtree of  $x$ ,
    - ▶ then  $\text{key}[y] \leq \text{key}[x]$
  - ▶ If  $y$  is in right subtree of  $x$ ,
    - ▶ then  $\text{key}[y] \geq \text{key}[x]$

$$\text{key}[\text{leftSubtree}(x)] \leq \text{key}[x] \leq \text{key}[\text{rightSubtree}(x)]$$

# Binary Search Trees: Summary

- ▶ Operations on binary search trees:
  - ▶ SEARCH  $O(h)$
  - ▶ PREDECESSOR  $O(h)$
  - ▶ SUCCESOR  $O(h)$
  - ▶ MINIMUM  $O(h)$
  - ▶ MAXIMUM  $O(h)$
  - ▶ INSERT  $O(h)$
  - ▶ DELETE  $O(h)$
- ▶ These operations are fast if the height of the tree is small

# Binary Search Trees: Best & Worst case

---

- ▶ All BST operations are  $O(h)$ , where  $h$  is tree depth
- ▶ Best case running time is  $O(\log N)$ 
  - ▶ Minimum  $h$  is  $\log N$  for a binary tree with  $N$  nodes
- ▶ Worst case running time is  $O(N)$ 
  - ▶ What happens when you Insert elements in ascending order?
  - ▶ **Insert: 2, 4, 6, 8, 10, 12 into an empty BST**

# Balancing Binary Search Trees

---

- ▶ We have seen that all operations depend on the depth of the tree.
- ▶ We don't want trees with nodes which have large height
  - ▶ This can be attained if both subtrees of each node have roughly the same height.
- ▶ We want a tree with small height
  - ▶ Our goal is to keep the height of a binary search tree  $O(\log N)$
- ▶ Many algorithms exist for keeping binary search trees balanced, such trees are called balanced binary search trees.
  - ▶ AVL (Adelson-Velskii and Landis) trees
  - ▶ B-trees
  - ▶ Red-black tree

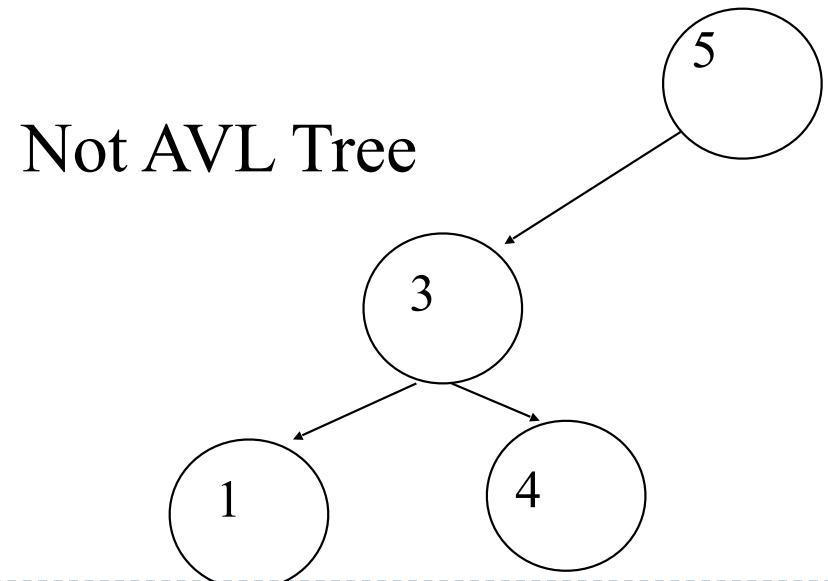

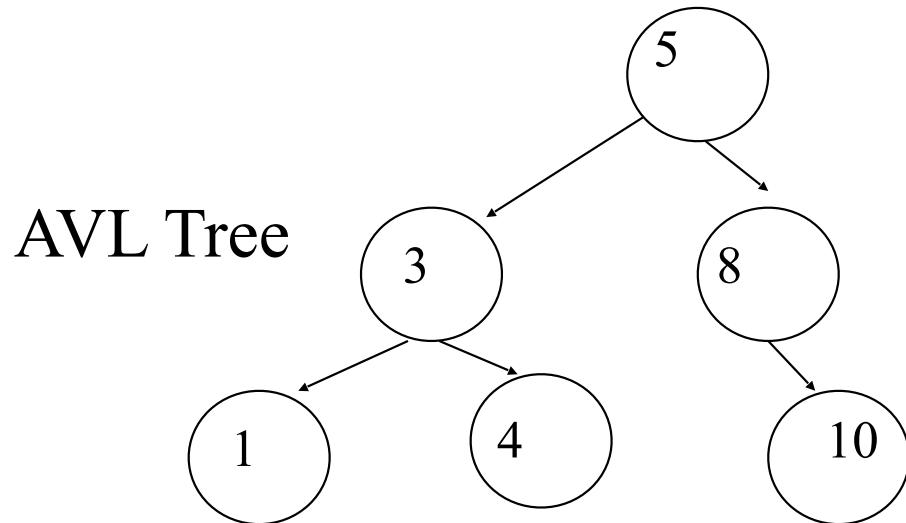

# AVL - Good but not Perfect Balance

---

- ▶ **AVL trees** are height-balanced binary search trees where the height of the two subtrees of a node differs by at most one
- ▶ **Balance factor** of a node
  - ▶  $\text{height}(\text{left subtree}) - \text{height}(\text{right subtree})$
- ▶ An AVL tree has balance factor calculated at every node
  - ▶ For every node, heights of left and right subtree can differ by no more than 1

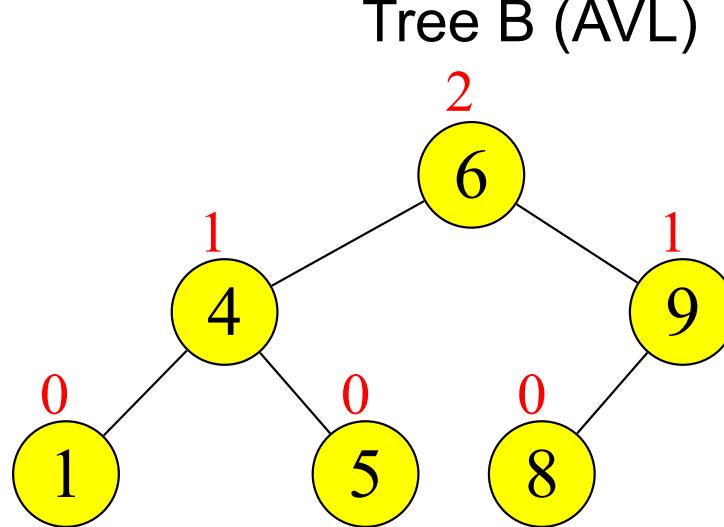

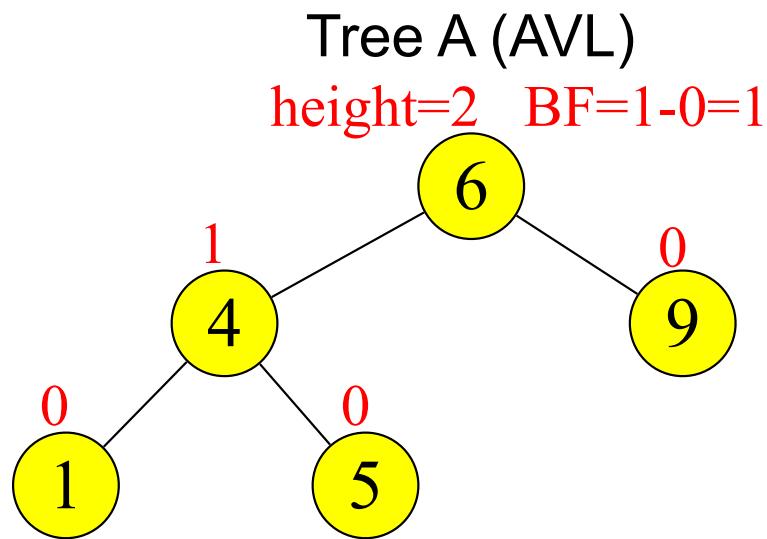

# AVL - Good but not Perfect Balance

- ▶ **AVL trees** are height-balanced binary search trees where the height of the two subtrees of a node differs by at most one
- ▶ **Balance factor** of a node
  - ▶  $\text{height}(\text{left subtree}) - \text{height}(\text{right subtree})$
- ▶ An AVL tree has balance factor calculated at every node
  - ▶ For every node, heights of left and right subtree can differ by no more than 1

# Node Heights

---

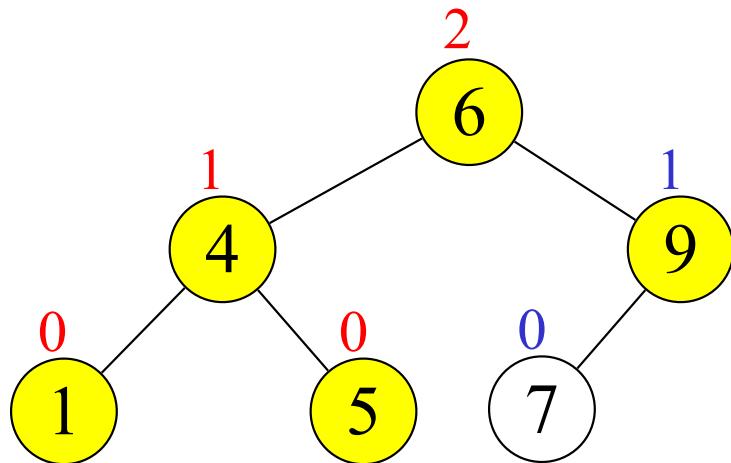

height of node =  $h$   
balance factor =  $|h_{\text{left}} - h_{\text{right}}|$   
empty height = -1

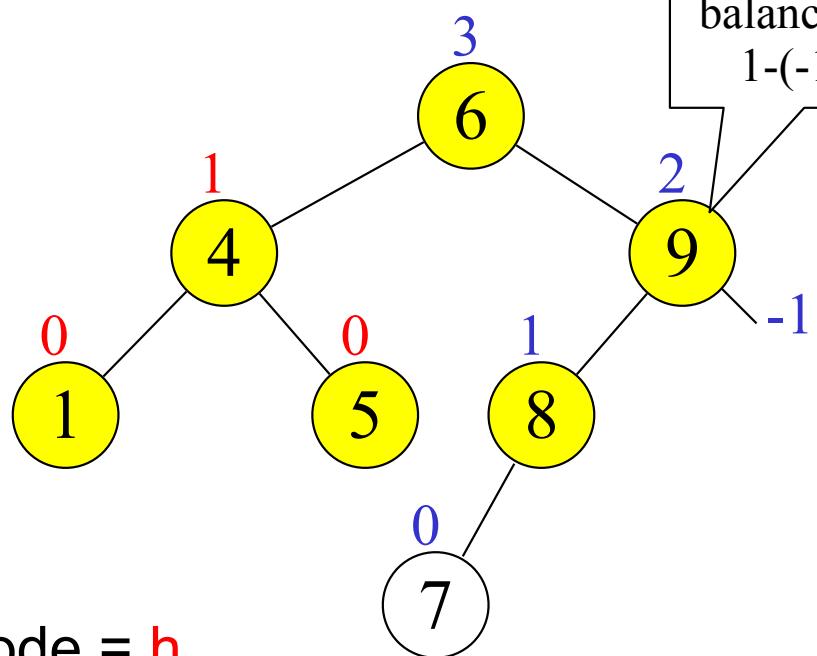

# Node Heights after Insert 7

Tree A (AVL)

Tree B (not AVL)

height of node =  $h$   
balance factor =  $|h_{\text{left}} - h_{\text{right}}|$   
empty height = -1

# Rotations

---

- ▶ When the tree structure changes (e.g., insertion or deletion), we need to transform the tree to restore the AVL tree property.
  - ▶ Since an insertion/deletion involves adding/deleting a single node, this can only increase/decrease the height of some subtree by 1
  - ▶ Thus, if the AVL tree property is violated at a node  $x$ , it means that the heights of  $\text{left}(x)$  ad  $\text{right}(x)$  differ by exactly 2.
  - ▶ Rotations will be applied to  $x$  to restore the AVL tree property/balance.
  - ▶ This is done using single rotations or double rotations.

# Insertion

---

- ▶ First, insert the new key as a new leaf just as in ordinary binary search tree
- ▶ Then trace the path from the **new leaf towards the root**. For each node  $x$  encountered, check if heights of  $\text{left}(x)$  and  $\text{right}(x)$  differ by at most 1.
- ▶ If yes, proceed to  $\text{parent}(x)$ . If not, restructure by doing **either a single rotation or a double rotation**.
- ▶ For insertion, once we perform a rotation at a node  $x$ , we won't need to perform any rotation at any ancestor of  $x$ .

# Insertion

---

- ▶ Let U be the node nearest to the inserted one which has an imbalance.
- ▶ There are 4 cases

**Outside Cases** (require single rotation) :

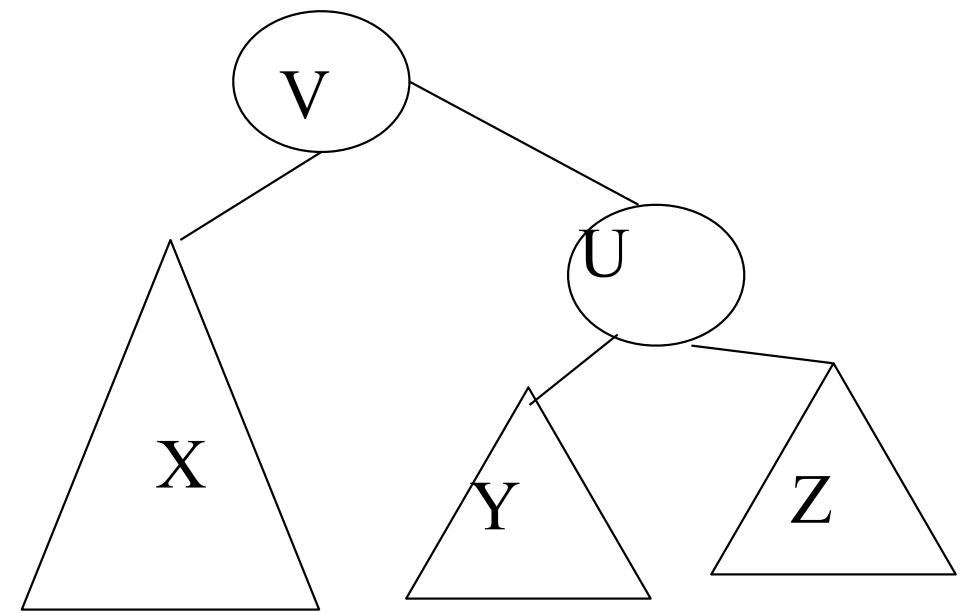

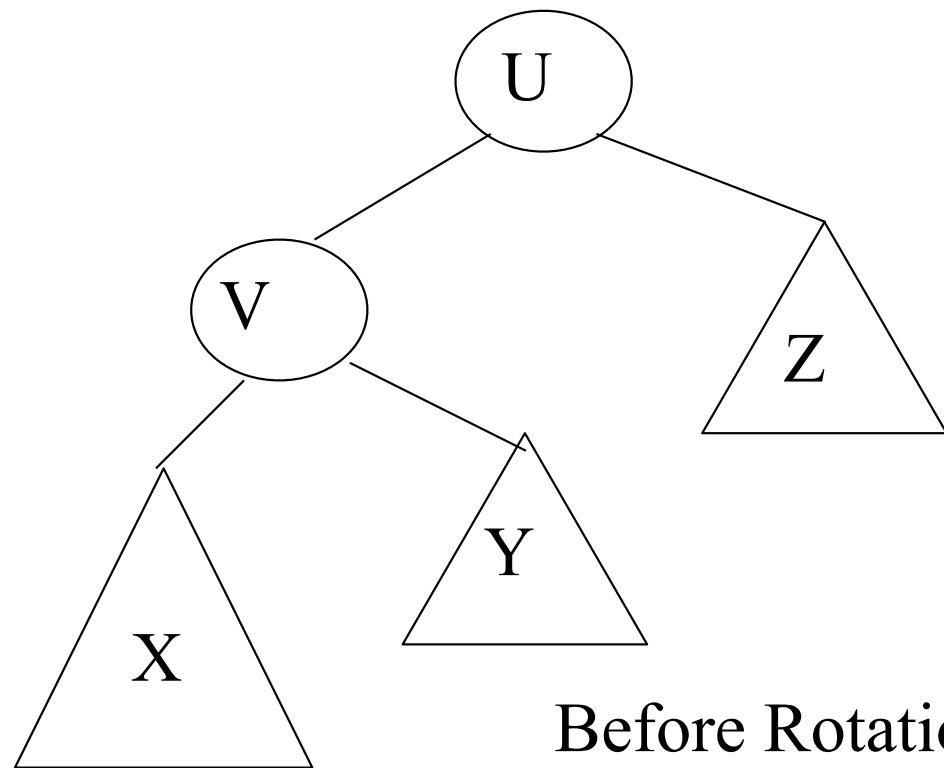

- ▶ Insertion in the **left** subtree of the **left** child of U
- ▶ Insertion in the **right** subtree of the **right** child of U

**Inside Cases** (require double rotation) :

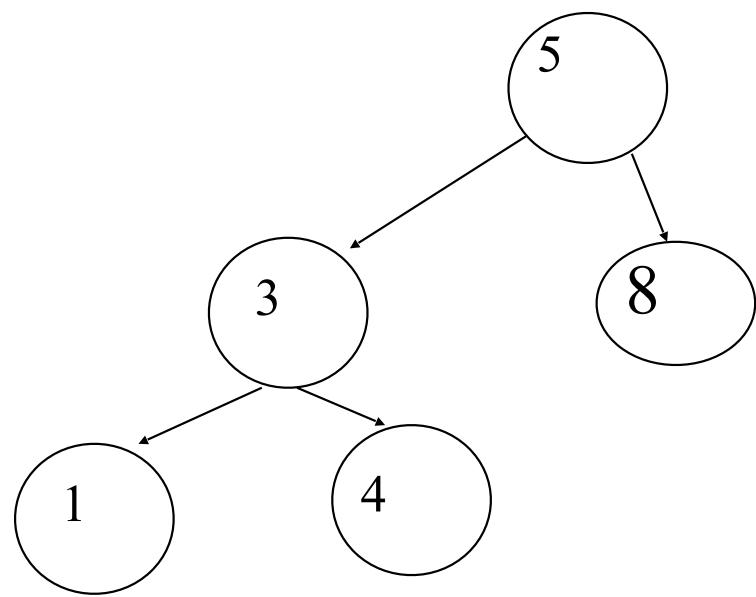

- ▶ Insertion in the **right** subtree of the **left** child of U
- ▶ Insertion in the **left** subtree of the **right** child of U

# Insertion in left subtree of left child

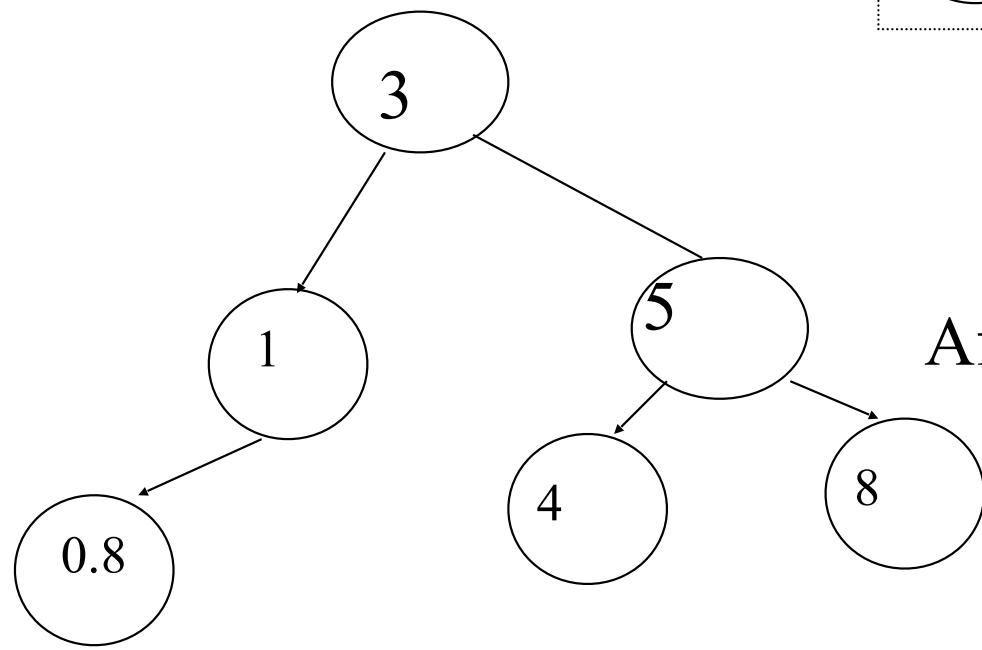

Single Rotation

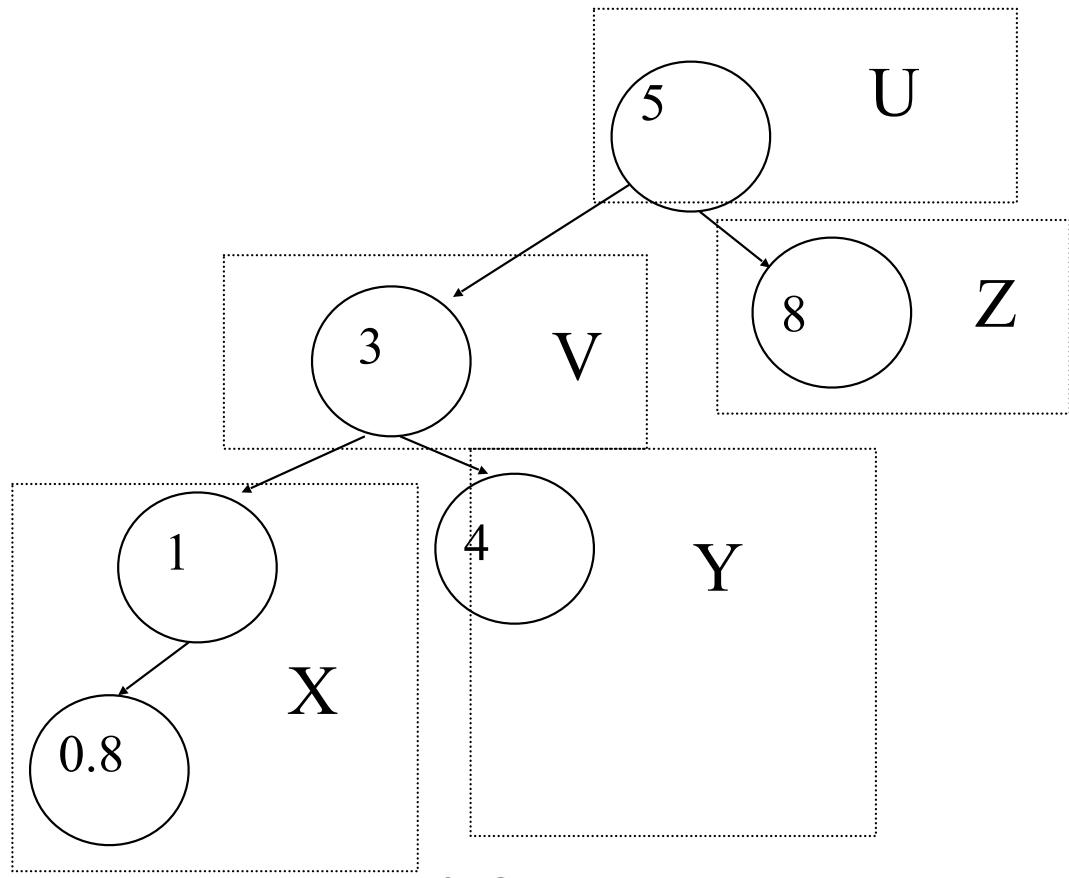

Let U be the node nearest to the inserted one which has an imbalance.

AVL Tree

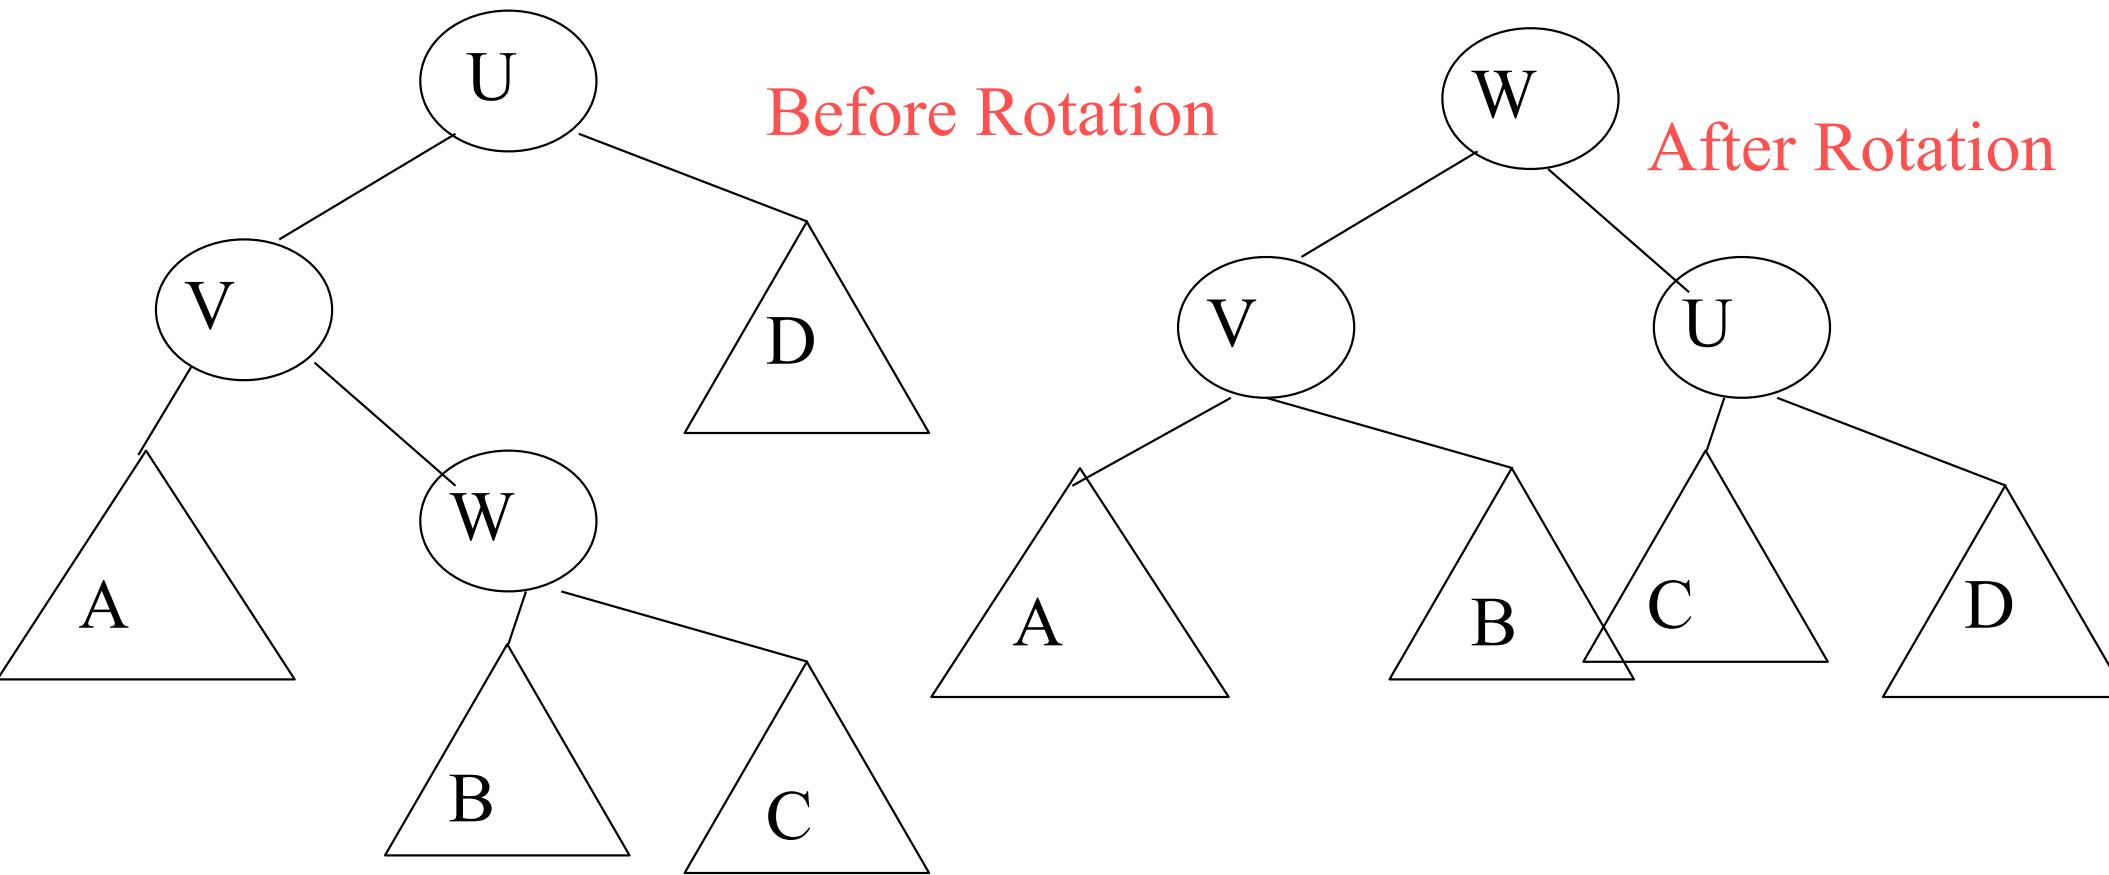

After Rotation

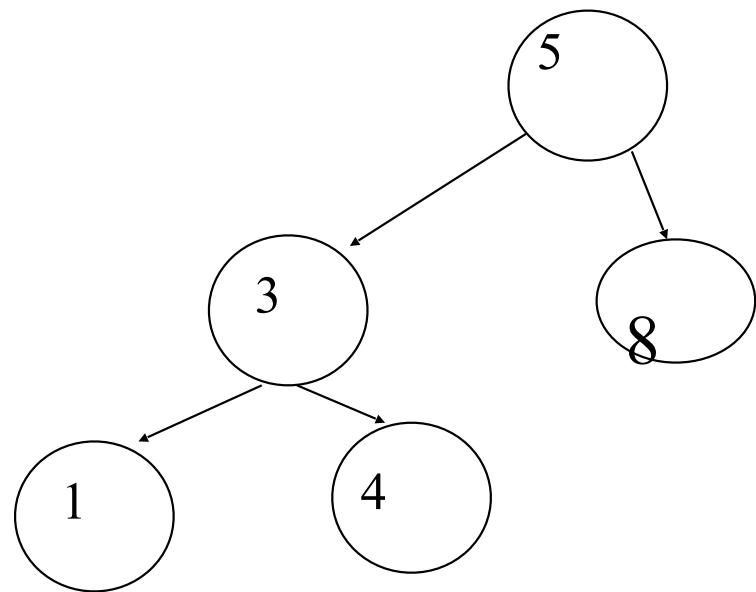

# Double Rotation

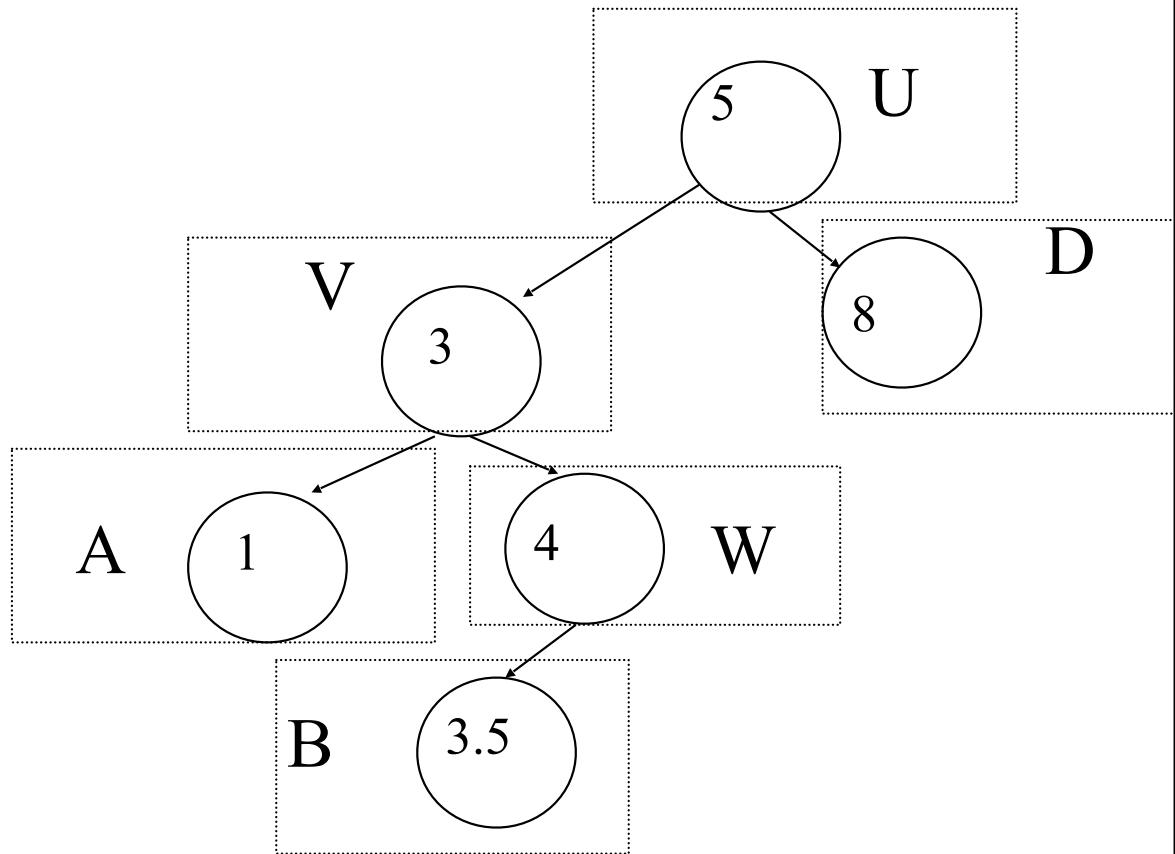

Suppose, imbalance is due to an insertion in the right subtree of left child

Single Rotation does not work!

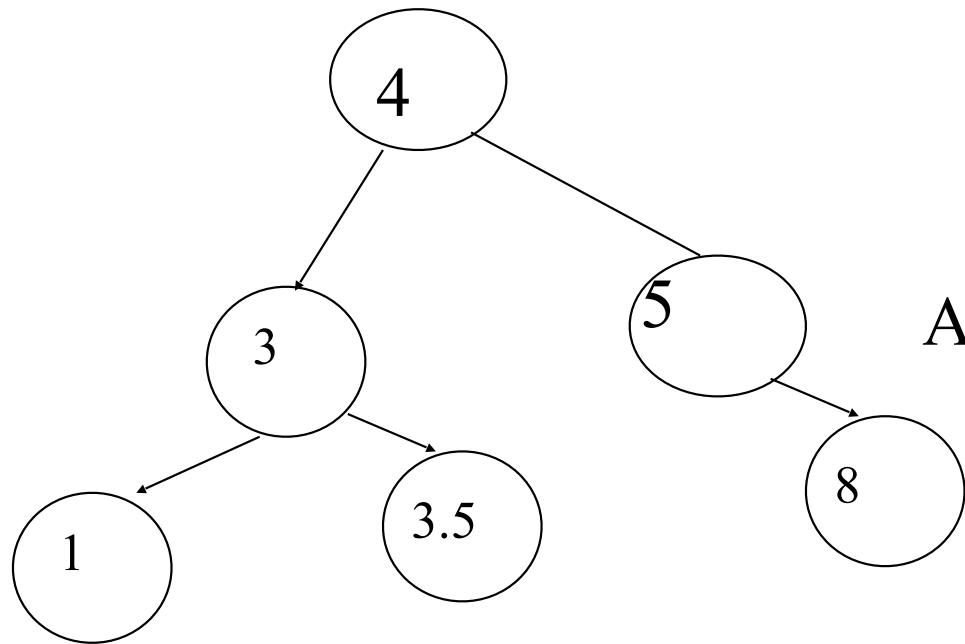

AVL Tree

Insert 3.5

After Rotation

# Extended Example

Insert 3,2,1,4,5,6,7, 16,15,14

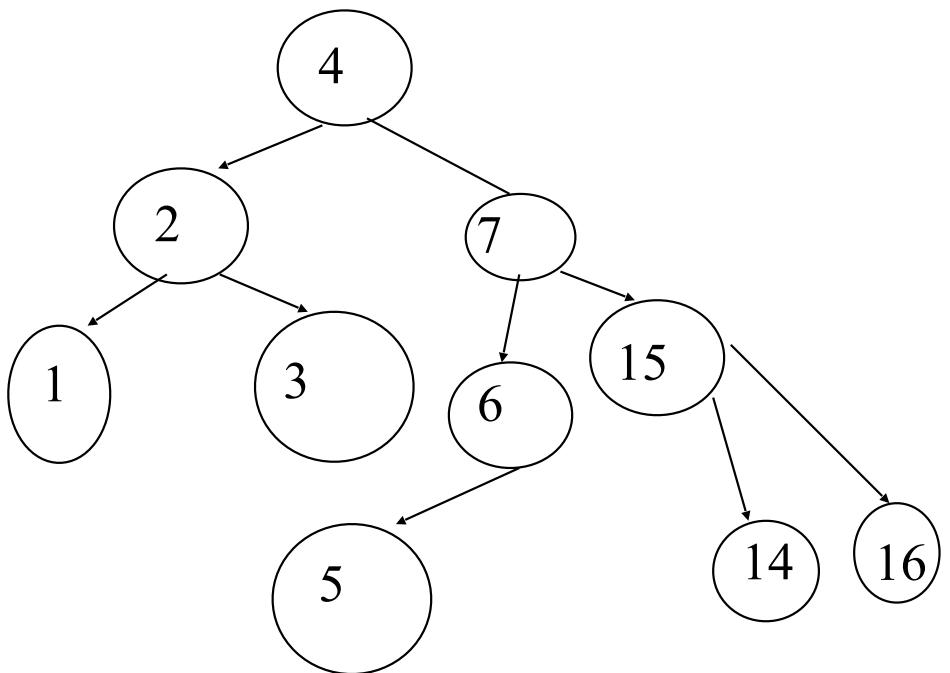

Fig 16

Deletions can be done with similar rotations

# Running Times for AVL Trees

---

- ▶ A single restructure/rotation is  $O(1)$
- ▶ Find/search is  $O(\log n)$ 
  - ▶ height of tree is  $O(\log n)$ , no restructures needed
- ▶ Insertion is  $O(\log n)$ 
  - ▶ initial find is  $O(\log n)$
  - ▶ Restructuring up the tree, maintaining heights is  $O(\log n)$
- ▶ Deletion is  $O(\log n)$ 
  - ▶ initial find is  $O(\log n)$
  - ▶ Restructuring up the tree, maintaining heights is  $O(\log n)$

# Midterm Review

- Complexity Analysis: Why we need to design algorithms, asymptotic notation
- Recurrences: Mathematical Induction, Recursion Trees, Master's Method
- Divide-and-Conquer: Maximum Sub-array, Sorting(Insertion Sort), Loop Invariants, Bubble Sort, Merge Sort
- HeapSort, Quicksort: Heap Data Structure, Hoare's (First element)/Lomuto (Last element), Average performance for quick sort
- Randomized Quick Sort, Sorting Lower Bound, Sorting in Linear Time, Order Statistics
- Hash Tables, Binary Search Tree and AVL Tree: Collisions and Universal Hashing, Insertion and Deletion in BSC,
